Abstract – Heat exchangers are thermal equipments very important for thermal and electrical power generation. Specialty literature emphasizes that more than half of primary energy consumed in a country goes to the final form of energy through a chain of transformations involving the average of 2-3 heat exchangers. The paper presents a 3D model of a counter flow plate heat exchanger and the numerical simulation of thermal regime of this heat exchanger, using finite element method.

Keywords: heat transfer, counter-flow heat exchanger, governing equation, finite element method, mesh.

1. COUNTERFLOW PLATE HEAT EXCHANGER

The studied heat exchanger is a pack of three stainless steel plates with gaskets. The hot water flows are in one direction in alternating chambers while the cold water flows are in counter flow in the other alternating chambers. The number of passes is 1 and the number of channels is $n_c = 2$, like in figure 1. The width of channel is 5 mm. The thermal agents are directed into their proper chambers either by a suitable gasket made from rubber EPDM. The stainless steel plate thickness is $\delta_p = 2$ mm.

The geometric dimensions of the plate are represented in figure 2.

2. MODELING AND SIMULATION OF HEAT EXCHANGER

Modeling of a process or equipment involves the execution of the next steps [1]:

- Physical modeling;
- Mathematical modeling;
- Simulation (numerical modeling);
- Visualization;
- Validation.

Mathematical modeling includes assignation of governing equations. The partial differential equations governing fluid flow and heat transfer include the continuity equation, the Navier-Stokes equations and the energy equation. These equations are intimately coupled and non-linear making a general analytic solution impossible except for a limited number of special problems, where the equations can be reduced to yield analytic solutions. Because most practical problems of interest do not fall into this limited category, approximate methods are used to determine...
the solution to these equations. There are numerous methods available for doing so. In this paper is used the Cosmos/Flow program.

Cosmos/Flow solves the mathematical equations which represent heat and momentum transfer in a moving fluid. The finite element method is used to discretize the flow domain, thereby transforming the governing partial differential equations into a set of algebraic equations whose solution represents an approximation to the exact analytical solution. It is used the iterative resolving technique: Newton – Raphson scheme, which assure a great rate of convergence.

2.1. Governing equations

The x-, y-, z-momentum equations:

\[
\frac{\partial \rho}{\partial t} + \frac{\partial (\rho u_i)}{\partial x_i} = \frac{\partial p}{\partial x_i} + \rho g_i + \sum_{i,j} S_{\omega_i} + S_{DR}
\]

The other two resistance types operate equally on each momentum equation.

The other source term is for rotating flow. This term can be written in general as:

\[
S_{\omega_i} = -2 \rho \omega_j \times \mathbf{v}_i - \rho \omega_j \times \mathbf{v}_i \times \mathbf{r}_i
\]

The variables from these equations are defined in Table 1.

Table 1 - Variables of the governing equations.

The equations describe the fluid flow and heat transfer under steady-state conditions for Cartesian geometries. For the turbulent flow, the solution of these equations would require a great deal of finite elements (on the order of \(10^6 - 10^8\)) even for a simple geometry as well as near infinitesimal time steps. COSMOS/Flow solves the time-averaged governing equations.

The time-averaged equations are obtained by assuming that the dependent variables can be represented as a superposition of a mean value and a fluctuating value, where the fluctuation is about the mean[2]. For example, the velocity component in y-direction can be written:

\[
V = V + v', \text{[m/s]}
\]
where \( V \) [m/s] – the mean velocity, \( v' \) [m/s] – the fluctuation about the mean. This representation is introduced into the governing equations and the equations themselves are averaged over time.

### 2.2. Discretization method

In COSMOS/Flow, the finite element method is used to reduce the governing partial differential equations (pdes) to a set of algebraic equations. The role of finite element method in numerical simulation is shown in figure 3. The dependent variables are represented by polynomial shape functions over a small area or volume (element). These representations are substituted into the governing pdes and then the weighted integral of these equations over the element is taken where the weight function is chosen to be the same as the shape function. The result is a set of algebraic equations for the dependent variable at discrete points or nodes on every element.

### 2.3. Boundary conditions and simplified hypothesis for modelling and simulation plate heat exchanger

The 3D model is realized in SolidWork. There are considered several simplified hypotheses:
- Hot water and cold water are Newtonian fluids;
- Turbulent flow is fully developed;
- Working fluids are incompressible;
- Steady state conditions.

The volumetric heat source term in the energy equation (5) is zero in this model.

The next boundary conditions are proposed:

<table>
<thead>
<tr>
<th>No.</th>

</tbody>
</table>

It calculates the heat flow of the hot water entering the heat exchanger, \( Q_1 \), with the next formula:

\[
Q_1 = \rho_1 \cdot c_{p1} \cdot V_1 \cdot T_1' \quad [W]
\]

where: \( \rho_1 = 988,611 \text{ m}^3/\text{kg}, \ c_{p1} = 4182,46 \text{ J/kgK} \) – thermo physical proprieties of water at temperature \( T_1' = 53°C \).

In the same mode, it calculates the heat flux of the cold water entering the heat exchanger, \( Q_2 \), with the relationship (8):

\[
Q_2 = \rho_2 \cdot c_{p2} \cdot V_2 \cdot T_2' \quad [W]
\]

where: \( \rho_2 = 999,8 \text{ m}^3/\text{kg}, \ c_{p2} = 4199,07 \text{ J/kgK} \) – thermo physical proprieties of water at temperature \( T_2' = 8°C \).

### 3. RESULTS DISPLAY

After the analysis was processed it can be visualized the results, under graphical form or numerical value. Analyze run for 100 iterations, in turbulence conditions. In figure 4 is presented the distribution of the nodal temperature on the heat exchange surface. Average temperatures are calculated at the outlet of hot water and cold water and it obtained the next values:

<table>
<thead>
<tr>
<th>No.</th>
<th>Fluid Description</th>
<th>U.M.</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Temperature</td>
<td>°C</td>
<td>17,8</td>
</tr>
<tr>
<td>2</td>
<td>Temperature</td>
<td>°C</td>
<td>39,6</td>
</tr>
</tbody>
</table>

The hot and cold fluid temperature distributions in the counter flow heat exchanger are shown in the figure 5.
LMTD – log mean temperature difference is computed under assumption of counter flow condition [3]:

$$LMTD = \frac{\ln \left( \frac{T_{1}'' - T_{2}''}{T_{1}''' - T_{2}'''} \right)}{ \frac{1}{T_{1}'''} - \frac{1}{T_{2}'''}} \text{ [C]}$$

In this case $LMTD = 11.46 \,^\circ C$.

The overall heat transfer coefficient $U$ is determined from heat transfer equation:

$$U = 4742 \, W/m^2K.$$ 

The distribution of resultant heat flux, $q$, in W/m², are shown in figure 6.

4. CONCLUSIONS

It is very important to realize the mesh with great accuracy. Values obtained for the temperature and heat flux are in accordance with technical possibilities of studied heat exchanger.

The model developed using the program COSMOS/Flow proves a very important tool for the study of heat transfer in a plate heat exchanger.
